

Parallel Programming Principle and Practice

Lecture 8 —Programming Using Message Passing Paradigm

Jin, Hai

School of Computer Science and Technology
Huazhong University of Science and Technology

Outline

- Principles of Message-Passing Programming
- The Building Blocks: Send and Receive Operations
- MPI: the Message Passing Interface
- Topologies and Embedding
- Overlapping Communication with Computation
- Collective Communication and Computation Operations
- Groups and Communicators

Principles of Message Passing Programming

- □ The logical view of a machine supporting the messagepassing paradigm consists of p processes, each with its own exclusive address space
- Each data element must belong to one of the partitions of the space; hence, data must be explicitly partitioned and placed
- ☐ All interactions (read-only or read/write) require cooperation of two processes the process that has the data and the process that wants to access the data
- These two constraints make underlying costs very explicit to the programmer

Principles of Message Passing Programming

- Message-passing programs are often written using the asynchronous or loosely synchronous paradigms
- In the asynchronous paradigm, all concurrent tasks execute asynchronously
- In the loosely synchronous model, tasks or subsets of tasks synchronize to perform interactions. Between these interactions, tasks execute completely asynchronously
- Most message-passing programs are written using the single program multiple data (SPMD) model

Outline

- Principles of Message-Passing Programming
- The Building Blocks: Send and Receive Operations
- MPI: the Message Passing Interface
- Topologies and Embedding
- Overlapping Communication with Computation
- Collective Communication and Computation Operations
- Groups and Communicators

The Building Blocks: **Send and Receive Operations**

- The prototypes of these operations are as follows send(void *sendbuf, int nelems, int dest) receive(void *recvbuf, int nelems, int source)
- Consider the following code segments

```
P0
                 P1
           receive(&a, 1, 0)
a = 100;
send(&a, 1, 1); printf("%d\n", a);
a = 0;
```

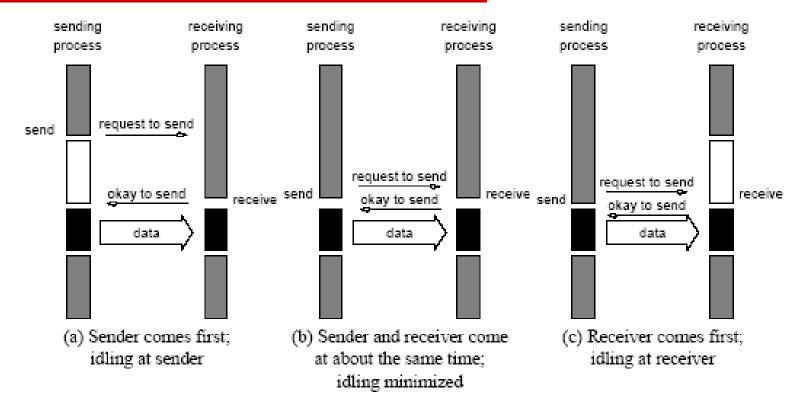

- The semantics of the send operation require that the value received by process P1 must be 100 as opposed to 0
- This motivates the design of the send and receive protocols

- □ A simple method for forcing send/receive semantics is for the send operation to return only when it is safe to do so
- In the non-buffered blocking send, the operation does not return until the matching receive has been encountered at the receiving process
- Idling and deadlocks are major issues with nonbuffered blocking sends

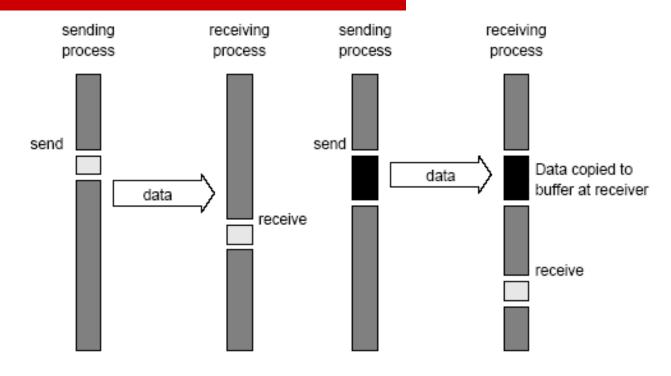

Handshake for a blocking non-buffered send/receive operation. It is easy to see that in cases where sender and receiver do not reach communication point at similar times, there can be considerable idling overheads. 華中科技大學 8

- A simple solution to the idling and deadlocking problem outlined above is to rely on buffers at the sending and receiving ends
- The sender simply copies the data into the designated buffer and returns after the copy operation has been completed
- The data must be buffered at the receiving end as well
- Buffering trades off idling overhead for buffer copying overhead

Blocking buffered transfer protocols:

- (a) in the presence of communication hardware with buffers at send and receive ends
- (b) in the absence of communication hardware, sender interrupts receiver and deposits data in buffer at receiver end

Bounded buffer sizes can have signicant impact on performance.

```
P<sub>0</sub>
                              P1
for (i = 0; i < 1000; i++) { for (i = 0; i < 1000; i++) {
    produce data(&a);
                                 receive(&a, 1, 0);
   send(&a, 1, 1);
                                  consume data(&a);
```

What if consumer was much slower than producer?

Deadlocks are still possible with buffering since receive operations block.

```
P<sub>0</sub>
                            P1
receive(&a, 1, 1);
                          receive(&a, 1, 0);
send(&b, 1, 1);
                           send(&b, 1, 0);
```

Non-Blocking **Message Passing Operations**

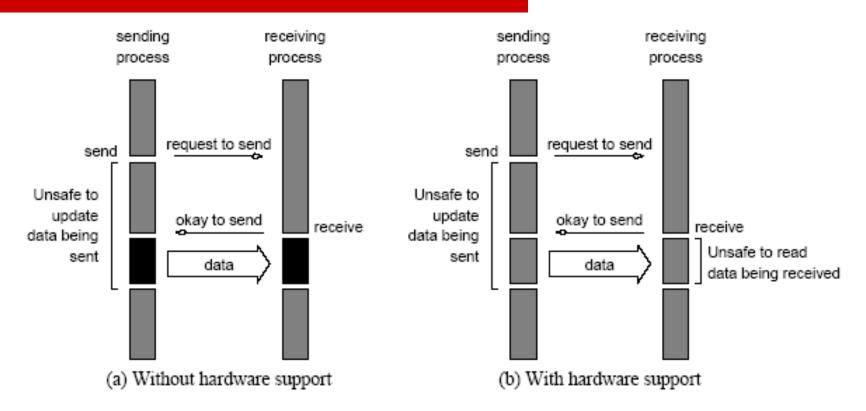

- The programmer must ensure semantics of the send and receive
- This class of non-blocking protocols returns from the send or receive operation before it is semantically safe to do so
- Non-blocking operations are generally accompanied by a check-status operation
- When used correctly, these primitives are capable of overlapping communication overheads with useful computations
- Message passing libraries typically provide both blocking and non-blocking primitives 单个科技大学 13

Non-Blocking **Message Passing Operations**

Non-blocking send and receive operations

- (a) in absence of communication hardware
- (b) in presence of communication hardware

Send and Receive Protocols

Blocking Operations

Non-Blocking Operations

Buffered

Sending process returns after data has been copied into communication buffer

Sending process returns after initiating DMA transfer to buffer. This operation may not be completed on return

Non-Buffered

Sending process blocks until matching receive operation has been encountered

Send and Receive semantics assured by corresponding operation

Programmer must explicitly ensure semantics by polling to verify completion

Space of possible protocols for send and receive operations

Outline

- Principles of Message-Passing Programming
- The Building Blocks: Send and Receive Operations
- MPI: the Message Passing Interface
- Topologies and Embedding
- Overlapping Communication with Computation
- Collective Communication and Computation Operations
- **Groups and Communicators**

MPI: Message Passing Interface

- MPI defines a standard library for message-passing that can be used to develop portable message-passing programs using either C or Fortran
- The MPI standard defines both the syntax as well as the semantics of a core set of library routines
- Vendor implementations of MPI are available on almost all commercial parallel computers
- It is possible to write fully-functional message-passing programs by using only the six routines

The Minimal Set of MPI Routines

MPI Init Initializes MPI

MPI Finalize Terminates MPI

MPI Comm size Determines the number of processes

MPI_Comm_rank Determines the label of calling process

MPI Send Sends a message

Receives a message MPI Recv

Starting and Terminating MPI Library

- MPI Init is called prior to any calls to other MPI routines. Its purpose is to initialize the MPI environment
- MPI Finalize is called at the end of the computation, and it performs various clean-up tasks to terminate the MPI environment
- The prototypes of these two functions are:

```
int MPI Init(int *argc, char ***argv)
int MPI Finalize()
```

- MPI Init also strips off any MPI related command-line arguments
- All MPI routines, data-types, and constants are prefixed by "MPI". The return code for successful completion is MPI SUCCESS

Communicators

- □ A communicator defines a communication domain a set of processes that are allowed to communicate with each other
- Information about communication domains is stored in variables of type MPI Comm
- Communicators are used as arguments to all message transfer MPI routines
- A process can belong to many different (possibly overlapping) communication domains
- MPI defines a default communicator called
 MPI COMM WORLD which includes all the processes

Querying Information

- ☐ The MPI_Comm_size and MPI_Comm_rank functions are used to determine the number of processes and the label of the calling process, respectively
- ☐ The calling sequences of these routines are as follows:

```
int MPI_Comm_size(MPI_Comm comm, int *size)
int MPI_Comm_rank(MPI_Comm comm, int *rank)
```

□ The rank of a process is an integer that ranges from zero up to the size of the communicator minus one

Our First MPI Program

```
#include <mpi.h>
main(int argc, char *argv[])
       int npes, myrank;
       MPI_Init(&argc, &argv);
       MPI_Comm_size(MPI_COMM_WORLD, &npes);
       MPI_Comm_rank(MPI_COMM_WORLD, &myrank);
       printf("From process %d out of %d, Hello World!\n",
               myrank, npes);
       MPI_Finalize();
```

Sending and Receiving Messages

- The basic functions for sending and receiving messages in MPI are the MPI Send and MPI Recv, respectively
- The calling sequences of these routines are as follows:

```
int MPI Send(void *buf, int count, MPI Datatype
datatype, int dest, int tag, MPI Comm comm)
int MPI Recv (void *buf, int count, MPI Datatype
datatype, int source, int tag,
MPI Comm comm, MPI Status *status)
```

- MPI provides equivalent datatypes for all C datatypes. This is done for portability reasons
- The datatype MPI BYTE corresponds to a byte (8 bits) and MPI PACKED corresponds to a collection of data items that has been created by packing non-contiguous data
- The message-tag can take values ranging from zero up to the MPI defined constant MPI TAG UB

MPI Datatypes

MPI Datatype	C Datatype		
MPI_CHAR	signed char		
MPI_SHORT	signed short int		
MPI_INT	signed int		
MPI_LONG	signed long int		
MPI_UNSIGNED_CHAR	unsigned char		
MPI_UNSIGNED_SHORT	unsigned short int		
MPI_UNSIGNED	unsigned int		
MPI_UNSIGNED_LONG	unsigned long int		
MPI_FLOAT	float		
MPI_DOUBLE	double		
MPI_LONG_DOUBLE	long double		
MPI_BYTE			
MPI_PACKED			

Sending and Receiving Messages

- MPI allows specification of wildcard arguments for both source and tag
- ☐ If source is set to MPI_ANY_SOURCE, then any process of the communication domain can be the source of the message
- ☐ If tag is set to MPI_ANY_TAG, then messages with any tag are accepted
- On the receive side, the message must be of length equal to or less than the length field specified

Sending and Receiving Messages

- □ On the receiving end, the status variable can be used to get information about the MPI Recv operation
- ☐ The corresponding data structure contains:

```
typedef struct MPI_Status {
int MPI_SOURCE;
int MPI_TAG;
int MPI_ERROR; };
```

□ The MPI_Get_count function returns the precise count of data items received

Avoiding Deadlocks

Consider:

```
int a[10], b[10], myrank;
MPI Status status;
MPI Comm rank (MPI COMM WORLD, &myrank);
if (myrank == 0) {
    MPI Send(a, 10, MPI INT, 1, 1, MPI COMM WORLD);
    MPI Send(b, 10, MPI INT, 1, 2, MPI COMM WORLD);
else if (myrank == 1) {
    MPI Recv(b, 10, MPI INT, 0, 2, MPI COMM WORLD);
    MPI Recv(a, 10, MPI INT, 0, 1, MPI COMM WORLD);
```

If MPI Send is blocking, there is a deadlock

Avoiding Deadlocks

Consider the following piece of code, in which process *i* sends a message to process i + 1 (modulo the number of processes) and receives a message from process i - 1 (module the number of processes)

```
int a[10], b[10], npes, myrank;
MPI Status status;
MPI Comm size (MPI COMM WORLD, &npes);
MPI Comm rank (MPI COMM WORLD, &myrank);
MPI Send(a, 10, MPI INT, (myrank+1)%npes, 1,
      MPI COMM WORLD);
MPI Recv(b, 10, MPI INT, (myrank-1+npes)%npes, 1,
      MPI COMM WORLD);
```

Once again, we have a deadlock if MPI Send is blocking

Avoiding Deadlocks

We can break the circular wait to avoid deadlocks as follows:

```
int a[10], b[10], npes, myrank;
MPI Status status;
MPI Comm size (MPI COMM WORLD, &npes);
MPI Comm rank (MPI COMM WORLD, &myrank);
if (myrank%2 == 1) {
      MPI Send(a, 10, MPI INT, (myrank+1)%npes, 1,
      MPI COMM WORLD);
      MPI Recv(b, 10, MPI INT, (myrank-1+npes)%npes, 1,
             MPI COMM WORLD);
else {
      MPI Recv(b, 10, MPI INT, (myrank-1+npes)%npes, 1,
             MPI COMM WORLD);
      MPI Send(a, 10, MPI INT, (myrank+1)%npes, 1,
      MPI COMM WORLD);
```

Sending and Receiving **Messages Simultaneously**

To exchange messages, MPI provides the following function:

```
int MPI Sendrecv(void *sendbuf, int sendcount,
 MPI Datatype senddatatype, int dest, int
 sendtag, void *recvbuf, int recvcount,
 MPI Datatype recvdatatype, int source, int recvtag,
 MPI Comm comm, MPI Status *status)
```

The arguments include arguments to the send and receive functions. If we wish to use the same buffer for both send and receive, we can use:

```
int MPI Sendrecv replace (void *buf, int count,
 MPI Datatype datatype, int dest, int sendtag,
 int source, int recvtag, MPI Comm comm,
 MPI Status *status)
```

Outline

- Principles of Message-Passing Programming
- The Building Blocks: Send and Receive Operations
- MPI: the Message Passing Interface
- Topologies and Embedding
- Overlapping Communication with Computation
- Collective Communication and Computation Operations
- Groups and Communicators

Topologies and Embeddings

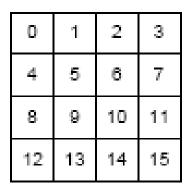

- MPI allows a programmer to organize processors into logical k-d meshes
- The processor ids in MPI COMM WORLD can be mapped to other communicators (corresponding to higher-dimensional meshes) in many ways
- The goodness of any such mapping is determined by the interaction pattern of the underlying program and the topology of the machine
- MPI does not provide the programmer any control over these mappings

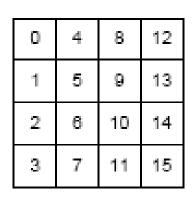

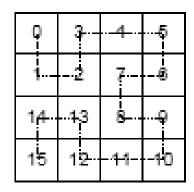

Topologies and Embeddings

(a) Row-major mapping

(b) Column-major

(c) Space-filling curve mapping

0	1	3	2
4	5	7	00
12	13	15	14
8	9	11	10

- Different ways to map a set of processes to a two-dimensional grid
 - (a) and (b) show a row- and column-wise mapping of these processes
 - (c) shows a mapping that follows a space-filling curve (dotted line)
 - (d) shows a mapping in which neighboring processes are directly connected in a hypercube

Creating and Using Cartesian Topologies

We can create cartesian topologies using the function:

```
int MPI Cart create (MPI Comm comm old, int ndims,
                   int *dims, int *periods, int reorder,
                   MPI Comm *comm cart)
```

This function takes the processes in the old communicator and creates a new communicator with dims dimensions

Each processor can now be identified in this new cartesian topology by a vector of dimension dims

Creating and Using **Cartesian Topologies**

Since sending and receiving messages still require (onedimensional) ranks, MPI provides routines to convert ranks to cartesian coordinates and vice-versa

```
int MPI Cart coord (MPI Comm comm cart, int rank, int maxdims,
                 int *coords)
int MPI Cart rank(MPI Comm comm cart, int *coords, int *rank)
```

The most common operation on cartesian topologies is a shift. To determine the rank of source and destination of such shifts, MPI provides the following function:

```
int MPI Cart shift (MPI Comm comm cart, int dir, int s step,
                 int *rank source, int *rank dest)
```

Outline

- Principles of Message-Passing Programming
- The Building Blocks: Send and Receive Operations
- MPI: the Message Passing Interface
- Topologies and Embedding
- Overlapping Communication with Computation
- Collective Communication and Computation Operations
- **Groups and Communicators**

Overlapping Communication with Computation

In order to overlap communication with computation, MPI provides a pair of functions for performing non-blocking send and receive operations

```
int MPI Isend(void *buf, int count, MPI Datatype datatype,
          int dest, int tag, MPI Comm comm,
          MPI Request *request)
int MPI Irecv(void *buf, int count, MPI Datatype datatype,
          int source, int tag, MPI Comm comm,
          MPI Request *request)
```

These operations return before the operations have been completed. Function MPI Test tests whether or not the nonblocking send or receive operation identified by its request has finished

```
int MPI_Test(MPI Request *request, int *flag,
   MPI Status *status)
```

MPI Wait waits for the operation to complete int MPI_Wait(MPI_Request *request, MPI Status *status)

Avoiding Deadlocks

Using non-blocking operations remove most deadlocks Consider:

```
int a[10], b[10], myrank;
MPI Status status;
MPI_Comm_rank(MPI COMM WORLD, &myrank);
if (myrank == 0) {
   MPI Send(a, 10, MPI INT, 1, 1, MPI COMM WORLD);
   MPI Send(b, 10, MPI INT, 1, 2, MPI COMM WORLD);
else if (myrank == 1) {
   MPI Recv(b, 10, MPI INT, 0, 2, &status, MPI COMM WORLD);
   MPI Recv(a, 10, MPI INT, 0, 1, &status, MPI COMM WORLD);
```

Replacing either the send or the receive operations with nonblocking counterparts fixes this deadlock 单个科技大学 38

Outline

- Principles of Message-Passing Programming
- The Building Blocks: Send and Receive Operations
- MPI: the Message Passing Interface
- Topologies and Embedding
- Overlapping Communication with Computation
- Collective Communication and Computation Operations
- Groups and Communicators

Collective Communication and **Computation Operations**

- MPI provides an extensive set of functions for performing common collective communication operations
- Each of these operations is defined over a group corresponding to the communicator
- All processors in a communicator must call these operations

The barrier synchronization operation is performed in MPI using:

```
int MPI Barrier(MPI Comm comm)
```

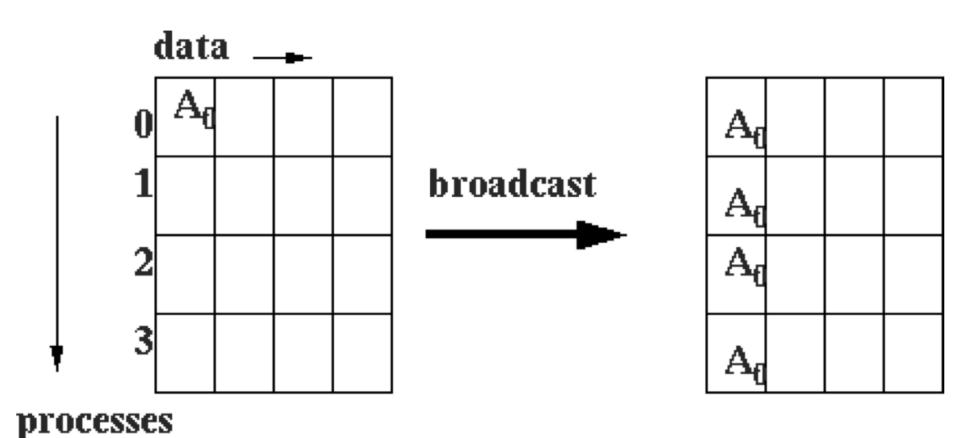

□ The one-to-all broadcast operation is

☐ The all-to-one reduction operation is:

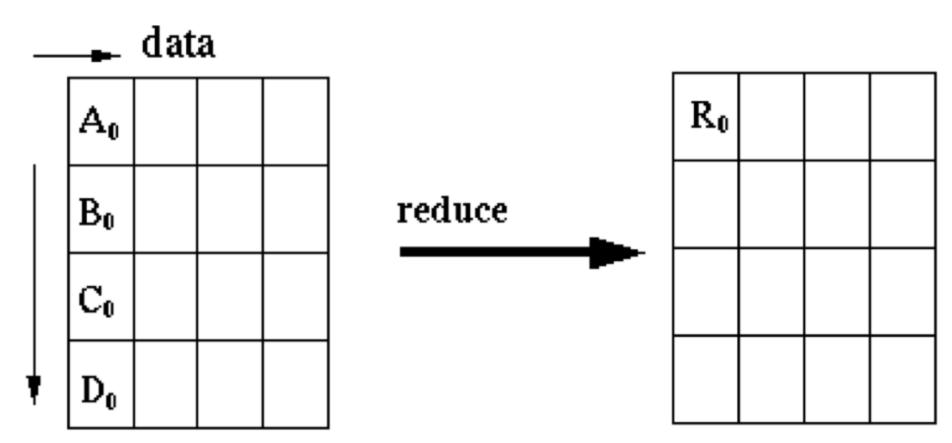

Broadcast: Effect

MPI_Reduce

processes

Predefined Reduction Operations

Operation	Meaning	Datatypes
MPI_MAX	Maximum	C integers and floating point
MPI_MIN	Minimum	C integers and floating point
MPI_SUM	Sum	C integers and floating point
MPI_PROD	Product	C integers and floating point
MPI_LAND	Logical AND	C integers
MPI_BAND	Bit-wise AND	C integers and byte
MPI_LOR	Logical OR	C integers
MPI_BOR	Bit-wise OR	C integers and byte
MPI_LXOR	Logical XOR	C integers
MPI_BXOR	Bit-wise XOR	C integers and byte
MPI_MAXLOC	max-min value-location	Data-pairs
MPI_MINLOC	min-min value-location	Data-pairs

- The operation MPI_MAXLOC combines pairs of values (v_i, l_i) and returns the pair (v, l) such that v is the maximum among all v_i 's and l is the corresponding l_i (if there are more than one, it is the smallest among all these l_i 's)
- □ MPI_MINLOC does the same, except for minimum value of

```
Value \begin{bmatrix} 15 \\ 0 \end{bmatrix} \begin{bmatrix} 17 \\ 11 \end{bmatrix} \begin{bmatrix} 12 \\ 3 \end{bmatrix} \begin{bmatrix} 17 \\ 4 \end{bmatrix} \begin{bmatrix} 11 \\ 5 \end{bmatrix}
```

```
MinLoc(Value, Process) = (11, 2)
MaxLoc(Value, Process) = (17, 1)
```

An example use of the MPI_MINLOC and MPI_MAXLOC operators

MPI datatypes for data-pairs used with the MPI MAXLOC and MPI MINLOC reduction operations

MPI Datatype	C Datatype		
MPI_2INT	pair of ints		
MPI_SHORT_INT	short and int		
MPI_LONG_INT	long and int		
MPI_LONG_DOUBLE_INT	long double and int		
MPI_FLOAT_INT	float and int		
MPI_DOUBLE_INT	double and int		

If the result of the reduction operation is needed by all processes, MPI provides:

☐ To compute prefix-sums, MPI provides:

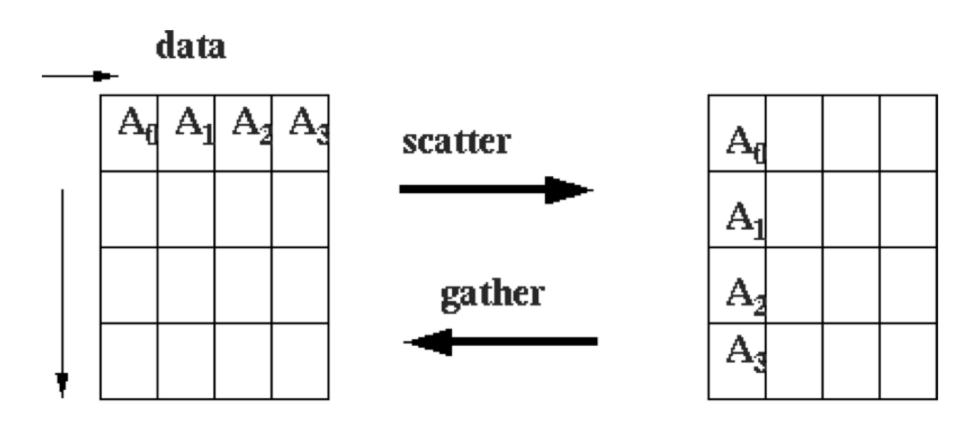

☐ The gather operation is performed in MPI using

□ The corresponding scatter operation

MPI_Gather and MPI_Scatter

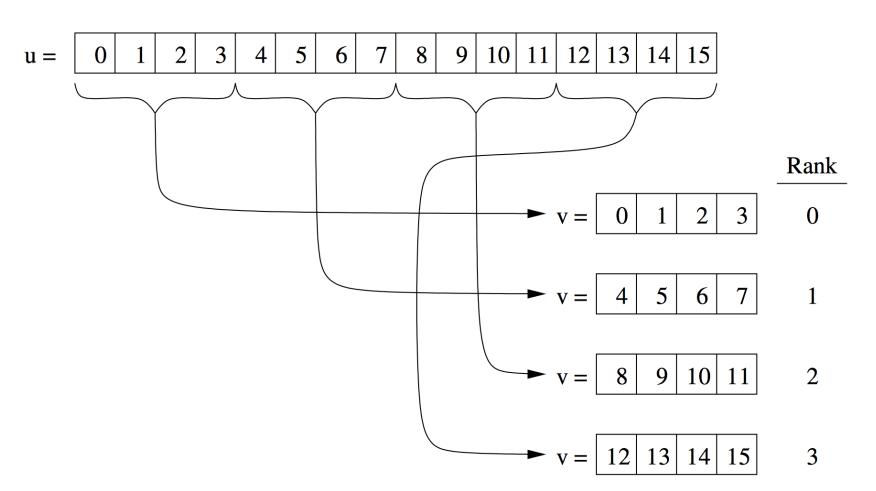

processes

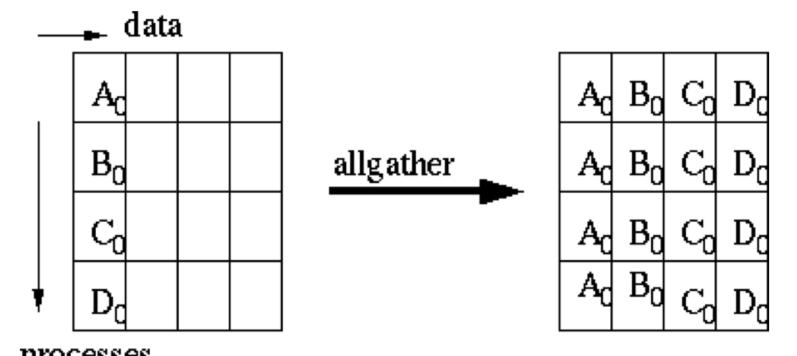

MPI Scatter()

MPI_Scatter(u, 4, MPI_INT, v, 4, MPI_INT, 0, MPI_WORLD_COMM);

☐ MPI also provides the MPI Allgather function in which the data are gathered at all the processes

51

☐ The all-to-all personalized communication operation is performed by:

 Using this core set of collective operations, a number of programs can be greatly simplified

Outline

- Principles of Message-Passing Programming
- The Building Blocks: Send and Receive Operations
- MPI: the Message Passing Interface
- Topologies and Embedding
- Overlapping Communication with Computation
- Collective Communication and Computation Operations
- **Groups and Communicators**

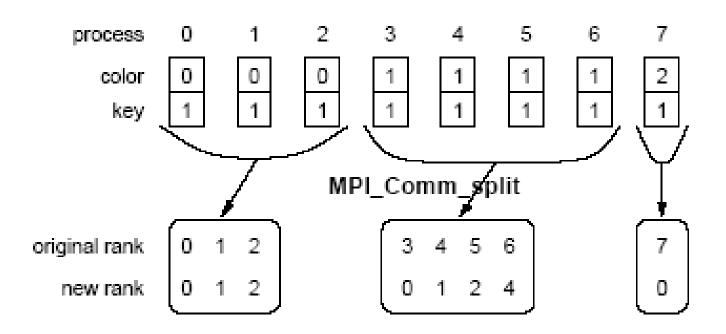

- In many parallel algorithms, communication operations need to be restricted to certain subsets of processes
- MPI provides mechanisms for partitioning the group of processes that belong to a communicator into subgroups each corresponding to a different communicator
- The simplest such mechanism is:

```
int MPI Comm split (MPI Comm comm, int color, int
                      MPI Comm *newcomm)
key,
```

This operation groups processors by color and sorts resulting groups on the key

Using MPI Comm split to split a group of processes in a communicator into subgroups

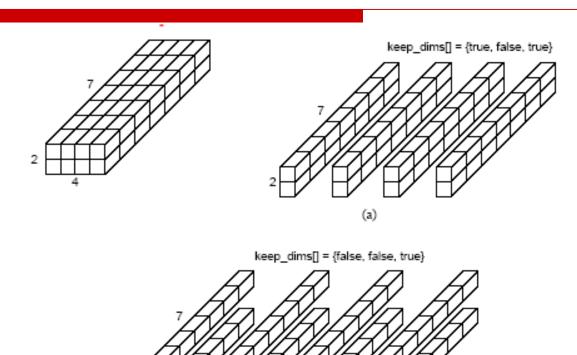

- In many parallel algorithms, processes are arranged in a virtual grid, and in different steps of the algorithm, communication needs to be restricted to a different subset of the grid
- MPI provides a convenient way to partition a Cartesian topology to form lower-dimensional grids:

- If keep_dims[i] is true (non-zero value in C) then the ith dimension is retained in the new sub-topology
- □ The coordinate of a process in a sub-topology created by MPI_Cart_sub can be obtained from its coordinate in the original topology by disregarding the coordinates that correspond to the dimensions that were not retained

- (a) Four subgroups of size 2 x 1 x 7
- (b) eight subgroups of size 1 x 1 x 7

Program

Invited Talks

EuroMPI is the preeminent meeting for users, developers and researchers to interact and discuss new developments and applications of message-passing parallel computing, in particular in and related to the Message Passing Interface (MPI). The annual meeting has a long, rich tradition, and has been held in European countries. In the 21st EuroMPI, the conference venue is in Kyoto, Japan, outside of Europe.

Following past meetings, EuroMPI/ASIA 2014 will continue to focus on not just MPI, but also extensions or alternative interfaces for high-performance homogeneous/heterogeneous/hybrid systems, benchmarks, tools, parallel I/O, fault tolerance, and parallel applications using MPI and other interfaces. Through the presentation of contributed papers, poster presentations and invited talks, attendees will have the opportunity to share ideas and
